

03 / 05 DELIVERABLE · ARCHITECTURE

AI Ecosystem Architecture Map

What each tool actually does, where AI enters the workflow, and where a human always stays in charge — laid out as one map instead of six separate mental models.

Status v1 Owner Chii / Chiibitsu Labs

The four layers

1 · VAULT

The knowledge foundation — client briefs, standards, the corpus.
Deliverable 1.

2 · WORKFLOW

The 12-step path a report actually travels, tool by tool.

3 · CONSISTENT OUTPUT

Lens-produced, standard-checked, on-brand.
Deliverable 2.

4 · THE INSTRUMENT

Reads the whole system to know when it's time to hire. Deliverable 5.

The 12-step workflow

Every handoff marked by who — or what — owns that step.

#	STEP	OWNER
1	Cycle opens on schedule (delivery log row created)	Human
2	Client context pulled from the vault	Vault
3	Data gathered (the "long queue" pain point — see Roadmap 2.5)	Human
4	First draft written against the encoded standard	AI
5	AI-QA pass 1 — markdown draft vs. the standard	AI
6	Internal review and edit	Human
7	Data and copy transferred into the Canva template	Human
8	Deck assembled, styled to brand	Human
9	AI-QA pass 2 — rendered deck vs. the standard (ship gate)	AI
10	Delivered to client	Human
11	Client reaction logged; revisions cycle back to step 6 if needed	Human
12	Session captured; real lessons promoted into the vault	Vault

Where AI enters, and where it doesn't

AI drafts and checks First-pass writing, and both quality gates. Anywhere the output can be measured against an explicit, written standard.	Humans always own Data gathering, client relationship, final visual assembly, and every ship decision. Nothing ships without a human clearing it — including what the AI-QA gate itself flags.
--	--

Tools, mapped to what they actually do

TOOL	FUNCTION
Claude (Enterprise)	Runs the three skills — draft, QA, capture
Google Drive	The vault — corpus storage and shared access
Sentimo + MCP	Data connection into the drafting step
Canva FRAGILE	Final visual assembly — flagged below as a named risk
Telegram + capchecker	Daily capacity check-in — the instrument's first feed
MS Office	Supporting document work where needed

Four risks, named on purpose

- **Canva fragility.** Crashes and access issues are real and already happening. Not replaced in this build — see the Roadmap for why, and what would change that call.
 - **Supplier and vendor pain.** Real, but a procurement problem, not an AI problem. Explicitly out of Core Build scope.
 - **Claude usage caps.** A ceiling worth watching as adoption scales past the first client.
 - **Corpus rot.** A vault that stops getting updated is worse than no vault — this is exactly what the capture loop in Deliverable 1 exists to prevent.
